## INTRODUCTION

Abandoned agricultural fields represent a major component of the landscape of the Hudson Valley of New York. Much of the structural diversity of the vegetation within this region can be attributed to the various stages of secondary succession that occur following abandonment of land from cultivation or pasture. The Mary Flagler Cary Arboretum encompasses 795 ha of land within the Mid-Hudson Valley, at elevations between 90 and 220 meters. The general geology, soils and climate of the Arboretum are described in Canham et al. (ms., in prep.). The forests and fields within the Arboretum represent a major resource for the research program of the Institute of Ecosystem Studies. The primary motivation for this study was to provide an inventory and analysis of the vegetation, environment and land-use history of the upland fields within the Arboretum in the hope that our results will aid both the management of those fields and promote their use in future research.

## METHODS

The present study was restricted to open fields located within upland areas of the Arboretum. Lowland fields along the floodplain of Wappinger Creek were excluded because they reflect a very different environment than the upland fields, and because they have been subjected to intensive management within the past decade.

## INVENTORY

Our inventory consists of descriptions of the land-use history, environment and current vegetation of the major upland fields within the Arboretum. The criteria for selecting fields for the inventory were designed to identify sites with the greatest potential for future research. These criteria were:

- (1) that a field was  $> 1$  ha in size;
- (2) that it had not been heavily disturbed or intensively managed for non-research uses in the past decade; and
- (3) that it did not contain plantings currently maintained by the Arboretum.

In addition, the fields around the Gifford House (south of Wappinger Creek) were excluded because of the likelihood of their use in public education programs.

The boundaries of each field were determined from stone walls, hedgerows and fences. In most cases, these features delimit areas of relatively uniform land-use, although the environment and vegetation within any given field is often strikingly heterogeneous. Using these criteria, 23 separate fields covering approximately 66 ha were identified and chosen for the inventory (Fig. 1). The fields occupy predominantly well-drained, rolling topography on either thin glacial till over bedrock or upper elevations of the thick layer of glacial outwash present in the valley bottoms. Elevations range from [ ] to [ ] m. Many of the fields have small local depressions that are poorly drained and may have standing water for some portion of the year. The vegetation of the fields ranges from almost exclusively herbaceous to complex mosaics of herbaceous and woody species. Many of the fields are in late stages of old field succession, with considerable invasion by tree and shrub species.

A variety of sources were used to compile a history of recent land-use for each field. Our efforts were focused primarily on identifying (1) agricultural uses immediately prior to abandonment, and (2) subsequent land-use. Our principal sources of information on agricultural practices prior to abandonment were interviews and field trips with several members of the families that farmed the land prior to abandonment (in particular, Mr. Jim Henry, Mr. Harry Pettit and Mr. Wendell Fowler). Historical records, including land deeds and agricultural censuses were used to provide background information on earlier agricultural practices. Mr. John Bouton, a former employee of both the Arboretum and the Davie Tree Company, provided details on management of the fields under Mrs. Cary. Present and past employees of the Arboretum were consulted for details of the management of each field following the formation of the Arboretum.

Our inventory of the vegetation within each field consists of a general description of the physical structure (particularly the relative distribution of trees, shrubs and herbaceous species) of the vegetation of the field, as well as lists of the major vascular plant species with an estimate of their abundance. Four abundance classes were used for trees and shrubs:

1. Rare - a single or few individuals of a species present in a field,
2. Low density - widespread throughout a field, but in low density,
3. Local patches - locally high densities of individuals or clones, but not found throughout the field, and
4. Abundant - relatively dense and widespread throughout the field.

The abundance classes record the abundance of a particular species relative to the overall abundance of that growth form (i.e. trees or shrubs) in the field. Trees species that were found primarily along field edges were specifically noted, since these trees often serve as sources of seed dispersal into the fields. The diversity and often inconspicuous nature of the herbaceous species precluded any attempt at a detailed abundance ranking. Instead, the dominant species were noted, and other unusual or characteristic species were listed separately. The field inventories were done during mid-summer (of 1985) in order to identify both early and late season species. Nomenclature follows Gleason and Cronquist (1963) unless otherwise noted.

## INTENSIVE STUDY

A subset of the inventoried fields was selected for more intensive, quantitative analysis. These sites were chosen to cover the range of vegetation, substrate, and land-use history encountered during the inventory. Seven major fields and two small (1 ha) fields from the different primary land parcels were chosen as the study sites for intensive research.

Five 200 m<sup>2</sup> circular plots (plot radius = 7.98m) were randomly located in each of the fields selected for study. Plot centers were randomly located using polar coordinates from an arbitrarily designated point of origin established at a prominent grid corner or map feature. Plot locations were rejected if the plot center fell within 10m of a road or track, or within 15m of the edge of the field, or in an active research area. The two 1 ha fields were treated as a single unit for the purposes of plot location due to the small size of these fields.

The projected cover of erect woody vegetation (erect shrubs and tree stems > 1m in height) was measured along four 7.5m line transects oriented in random

compass directions from the plot center. Adjacent transects were separated by at least  $30^{\circ}$ . The presence of species of trees and shrubs found within the plot but not encountered along the line transects was also recorded. Projected cover of herbaceous species and creeping woody plants was sampled using two  $1\text{ m} \times 0.5\text{ m}$  rectangular quadrats located at random distances along each of the four line transects. The cover of bare rock, litter, bare soil, mosses and lichens, as well as the density of tree seedlings, was also recorded. A complete list of herbaceous species present in the  $200\text{ m}^2$  plot was also compiled.

For each tree species, the densities of saplings (tree stems  $> 1\text{ m}$  in height and  $< 10\text{ cm}$  DBH) within the entire  $200\text{ m}^2$  plot were recorded in 2 cm DBH size classes. The actual DBH of tree-sized stems (stems  $> 10\text{ cm}$  DBH) were recorded individually by species.

The physical environment of each plot was characterized by recording descriptive information, including the slope, principal aspect, and slope position of the overall plot. Soil was collected for chemical analyses by removing cores from the top 10 cm of mineral soil at 5 randomly located points within each plot.

Two-way indicator species analysis (TWINSpan) (Hill 1979) was used to identify levels of similarity in vegetation between plots both within a given field and between different fields.

### LAND USE HISTORY

In many ways the Arboretum provides a microcosm of the landscape of southern New England. The present composition and structure of both fields and forests can be traced to the waxing and waning of agricultural practices and land use history over the past 3 centuries. For this report, we have concentrated on the period beginning immediately before agricultural abandonment.

### RECENT AGRICULTURAL HISTORY

Prior to their acquisition by the Melbert and Mary Flagler Cary, the fields included in this study were part of farms owned by the Henry, Chase, Pettit, and Saccomanda families. The farms were primarily devoted to dairy and cattle, and although some land was cultivated, crop yields were largely devoted to the support of livestock. The typical dairy herd averaged about 100 head, requiring about 15 ha. of pastureland. Pasturing usually occurred on land too steep or rocky for conventional tilling, while more suitable land was usually used for producing crops or hay. Much of the land remained in pasture permanently, with little improvement beyond clearing. Thus, these fields often supported populations of the native grasses of the region.

Crop rotation was commonly practiced to maintain soil fertility. The principal crop rotation cycle consisted of one year of corn followed by a year of oats, then three years of hay. Corn was grown to be used as grain and livestock feed and silage, oats were threshed to serve as horse and cattle feed, and hay was stored for silage and bedding. Rye and wheat were also occasionally planted in small amounts, but barley was rarely ever planted. Conventional tillage by horse and plow was standard, and by the time tractors were beginning to be used in the late 1930's, most of this land was already fallow.

## ABANDONMENT AND POST-AGRICULTURAL HISTORY

By 1930, the Cary's had acquired most of the land surrounding the Canoe Hills, but they permitted the farmers who had sold the land to remain as tenants for as long as they wished, continuing their farming operations much as they had done in the past. The Chase farm was abandoned first, in 1932, but the lower section of this property continued to be pastured by the Henry's. The Henry's left soon after this in the early 1930's, after which their property was leased to W. Braddock. He maintained the livestock, but there was little use of the land, even for pasturing. When he left after 4-5 years, the next tenants did not use the farm at all, and simply let the land become fallow. The Saccomanda dairy farm was not sold to the Carys until 1937, who chose not to remain as tenants and left about the same time. The Pettit farm continued to operate until late in 1939. By 1940, all agricultural use of the lands included in this study had ceased. Following the departure of the Pettits, it appears that there was little, if any, management of the land for the next 20 years.

Beginning in the early 1960's, Mary Flagler Cary employed a number of workers from the Davie Tree Company for a variety of projects, including pruning, clearing brush, cutting vistas, and moving trees. This work was concentrated around the Tea House Hill, consequently, most of the fields were left undisturbed. These activities continued until Mrs. Cary's death in 1967 (J. Bouton, pers. comm.).

Dominance of herbaceous vegetation in some of the old fields was preserved throughout the 1970's by mowing ("brush-hogging") that cut back invading woody plants. A small tractor was used to pull a hedge-cutting rig set at approximately half a meter above the ground. Larger shrubs and saplings were sometimes removed with a chain saw or by axe. Cutting was usually done once in the late spring, which allowed the herbaceous species to grow back later in the summer. Cutting was occasionally repeated in the late summer if time permitted. This practice inadvertently favored woody species which could rapidly spread vegetatively from a perennial root stock, most notably smooth sumac (*Rhus glabra*) and black locust (*Robinia pseudoacacia*), while selecting against more slowly invading tree species such as maples and oaks.

Some of the fields have been used since 1977 for studies of white-tailed deer and their effect on vegetation. In several fields these studies have included management practices designed to regenerate clones of succulent woody species, primarily smooth sumac, through the cutting of old clones. This management has been largely concentrated near stone walls and field edges, leaving other areas of a field undisturbed.

## ANALYSIS OF THE VEGETATION, ENVIRONMENT AND LAND-USE HISTORY OF THE UPLAND FIELDS

Characteristics of the 23 major upland fields are summarized in Table 1. The 40 intensively sampled plots were distributed in 8 fields that reflect the range of environmental conditions and land-use history encountered in the 23 fields. The intensively sampled plots allow a limited but quantitative analysis of relationships between vegetation, environment and land-use history in the upland fields of the Arboretum.

Two species - a shrub (*Cornus racemosa*, gray dogwood) and a grass (*Andropogon scoparius*, little bluestem) - are abundant throughout the old fields (Table 2). Gray dogwood was present in 85% of the plots, covering as much as 74% of a given plot (mean % cover = 14.6%). Little bluestem was present in 97.5% of the plots, covering as much as 76% of a plot (with a mean cover of 31.9%). The next most abundant herbaceous and woody species (species of *Solidago* and *Juniperus virginiana* respectively) had much more restricted distributions and much lower average cover values (Table 2).

Although the presence of little bluestem and gray dogwood provides a strong common element among all of the fields, classification of the fields using TWINSpan does allow the objective identification of relatively distinct groups of plots (Figure 2). The distribution of species among the 40 plots is given in Table 3. The 4 major groups of plots identified by the classification procedure appear to represent 4 relatively distinct combinations of environment and land-use history. The fact that most but not all of the separate plots from within a given field were placed in the same group by TWINSpan supports the assumption that there is significant environmental heterogeneity within fields, but a more general similarity among plots within a field as a result of a common land-use history.

The first major group identified by the classification procedure is a set of 7 plots, including all 5 of the plots from field #460, and 1 plot each from fields #710 and #720. Both gray dogwood and little bluestem are common in these fields (Table 3), but this set of plots is distinctive in the presence of 3 woody species that are characteristic of dry and infertile soils - *Betula populifolia* (gray birch), *Quercus ilicifolia* (scrub oak) and *Vaccinium vacillans* (early low blueberry). The virtual absence of any of the species of *Solidago* (goldenrods) (Table 3) also suggests that these sites are drier than most of the upland fields. Field #460 occupies relatively level terrain on glacial outwash deposits, with soils that are largely Hoosic gravelly loams. Fields #710 and #720 are both mapped as predominantly Nassau slaty silt loams derived from a thin layer of glacial till. We could not conclusively identify the agricultural use of field #460 prior to abandonment of the field in 1939, however fields #710 and #720 were both used as pasture prior to abandonment in 1932. The most distinctive aspect of land-use history for these three fields has been the virtual absence of any management since abandonment in the 1930's. While invasion of the fields by gray birch and scrub oak is responsible for the distinctiveness of the vegetation in field #460, the absolute rate of invasion of the field by woody plants has been remarkably low. Although it has been almost 50 years since the field was abandoned, the total cover of woody plants was greater than 15% in only 1 of the 5 plots within the field.

The second set of plots identified by TWINSpan can be best described as red cedar (*Juniperus virginiana*) woodlands. The group consists of 4 plots from field #710, 4 plots from field #123 and one plot each from fields #715 and #720. The plots, particularly those from field #710, have relatively dense populations of red cedars reaching 10 m in height over an herbaceous layer dominated by little bluestem. The plots occur on a variety of soils (Table 1), and were primarily used for pasture prior to abandonment during the 1930's. All of the 4 fields have received little, if any, management or human disturbance since abandonment. The average cover of tree and shrub species is greater in this group of plots than any other group (Figure 2), with almost

half of the total cover of woody plants contributed by red cedar. However, tree species that might eventually form a closed hardwood canopy are still uncommon and largely restricted to the edges of the fields.

The largest group of plots identified by TWINSPAN is a set of 18 plots, primarily from fields cultivated as part of the Henry farm (fields #904, #937, and #960). The fields are currently dominated by little bluestem, gray dogwood, a number of species of goldenrods (particularly Solidago graminifolia and Solidago rugosa) and both creeping and erect species of raspberries (Rubus spp.). In addition to the history of cultivation prior to abandonment in the mid 1930's, two of the fields (#937 and #960) were brush-hogged between 1973 and 1982 both to control woody invasion and for research purposes. Despite (or more likely, because of) these activities, this set of plots had the highest average cover of shrubs (Figure 2). Most of the plots are on shallow soils derived from a thin layer of glacial till over bedrock.

The final group of plots identified by TWINSPAN is the set of 5 plots from field #177. This field is the most distinctive of any of the fields surveyed for the inventory. It was used regularly as a hay field between 1961 and 1968, and was mowed regularly until 1982. The grass Phleum pratense (timothy, presumably sown for hay) and Galium mollugo (an introduced, weedy species of bedstraw) are the dominant species in these plots. Both little bluestem and gray dogwood are only sparsely distributed in this field.

## AN INVENTORY OF THE MAJOR UPLAND FIELDS

A map showing the locations of each of the 23 major upland fields within the Arboretum is provided in Figure 1. Characteristics of the vegetation, environment and history of the 23 fields are also summarized in Table 1. The remainder of this section of the report provides the more detailed inventory of each of the fields.

### INDIVIDUAL FIELD SUMMARIES

#### FIELD #123

##### Vegetation Structure

The field edges are amorphous, becoming open woods. Trees are relatively dense, large (some over 10m in height), and dominating in an open canopy. Hardwoods are most common toward the edges, with red cedar abundant in the open areas. The shrub layer is patchily distributed and mostly composed of solitary or clumped individuals present in open areas with the mixed herbaceous layer of grasses and broad-leaved plants abundant throughout the field.

##### Environmental Parameters

Hilltops and east- to southeast-facing hillsides form the terrain, sloping up to 15°. Most of the well-drained soil is acid Hoosic gravelly loam, along with some Wassaic stony loam, which is more neutral and underlain by limestone bedrock. Exposed rock is sparsely present on the steep hillside in the northwest corner.

##### Historical Information

The land was part of the Saccomanda dairy farm, and may have been used for pastureland at that time. The field has not been managed or used since it was abandoned in the late 1930's.

##### Species List

###### TREES

###### ABUNDANT:

Juniperus virginiana  
Acer rubrum

###### LOW DENSITY:

Cornus florida  
Prunus serotina  
Quercus velutina  
Ailanthus altissima

###### LOCAL PATCHES:

Populus tremuloides (edge)

###### RARE:

Fraxinus americana  
Quercus rubra  
Quercus prinus  
Acer saccharum  
Pyrus malus  
Pinus strobus

## SEEDLINGS

ABUNDANT:  
Juniperus virginiana

LOW DENSITY:  
Fraxinus americana  
Quercus velutina

LOCAL PATCHES:  
Populus tremuloides

RARE:  
Ulmus americana  
Quercus rubra  
Quercus prinus  
Carya glabra  
Pinus strobus

## SHRUBS (t= thicket, s= solitary, v= vine, c= creeping)

ABUNDANT:  
Cornus racemosa (s,t)

LOW DENSITY:  
Rhus glabra (s,t)  
Juniperus communis (s)

LOCAL PATCHES:  
Rubus sp. (c)  
Toxicodendron radicans (c)

RARE:  
Lonicera morrowii (s)  
Vaccinium vacillans (s)  
Rosa sp. (s)  
Rhamnus cathartica (s)  
Cornus amomum (s)  
Vaccinium stamineum (s)  
Viburnum dentatum (s)  
Parthenocissus quinquefolia (c)

## HERBACEOUS PLANTS

DOMINANTS: Andropogon scoparius, Solidago sp., Carex sp., Anthoxanthum odoratum

OTHERS: Pycnanthemum flexuosum, Rudbeckia hirta, Achillea millefolium, Prunella vulgaris, Anaphalis margaritacea, Hypericum perforatum, Trifolium agrarium, Hieracium florentinum, Rumex acetosella, Asclepias sp., Dianthus armeria, Aster sp., Centaurea jacea, Lobelia spicata

## FIELD #130

Vegetation Structure

The site is a complex mix of woody and herbaceous plants, with shrubs patchily distributed in an herbaceous matrix. The hilltops are dominated by grasses, with shrubs dominant elsewhere. Trees and seedlings are present throughout, particularly on the periphery of the field and in hedgerows and local depressions. Patches of bare soil or lichens are present on the hilltops.

Environmental Parameters

The terrain is composed of hilltops at the southwest edge divided by a depression between a south-facing hillside to the northeast. Slopes are moderate, ranging up to 20° down to a stream to the north.

Historical Information

The site was used as pastureland for the nearby Saccomanda dairy farm up until abandonment in 1937, and has remained untouched since that time.

OTHERS: Lysimachia quadriflora, Rudbeckia hirta, Achillea millefolium,  
Chrysanthemum leucanthemum, Dianthus armeria, Dactylis glomerata, Potentilla  
simplex, Trifolium agrarium, Erigeron strigosus, Erigeron annuus, Galium  
mollugo, Trifolium pratense, Sisyrinchium sp., Poa pratensis, Potentilla recta,  
Silene cucubalus, Juncus tenuis, Rumex acetosella  
 RARE:

### FIELD #141

#### Vegetation Structure

Patches of trees up to 8m in height dominate the field. Juniperus virginiana is abundant throughout the site, with tree seedlings and saplings common. Shrubs are also common, solitary or arranged in low clumps < 1.5 m high, rarely in thickets and never dense. The herbaceous cover is not complete, with bare soil between grass clumps and mosses, particularly at the south end of the field.

#### Environmental Parameters

The topography is mostly steep upper hillsides on east- and southeast-facing slopes reaching 25°. Shallow Nassau slaty silt loams (underlain by shale < 50 cm deep) along with some deep Hoosic gravelly loams are present at the site. These well-drained soils are characteristic of till and outwash soils in the area, respectively. Exposed bedrock is concentrated in the center and upper areas of the hillside.

#### Historical Information

This site was probably pastured until 1937 (before abandonment) as part of the working dairy farm which occupied the present greenhouse area. A stone wall is located nearby in the woods to the south.

DOMINANTS: Shizachyrium scoparius

OTHERS: Lycopodium complantum, Apocynum androsaemifolium, Rumex acetosella,  
Fragaria virginiana, Hieracium florentinum, Stellaria graminea, Verbascum  
thapsis, mosses, lichens (Cladonia cristatella and other Cladonia)

## FIELD #177

Vegetation Structure

The vegetation is dominated by mixed herbaceous and creeping plants; shrubs are rare and primarily found near the field periphery. A small patch of trees and shrubs is located at the extreme southwest corner.

Environmental Parameters

The site is flat, located on a hilltop with minor local depressions. The soil is a deep, acid, Hoosic gravelly loam.

Historical Information

The Saccomanda dairy farm used the land for pasturing before its abandonment in 1937. This field was regularly hayed between 1961 and 1968, and either hayed or mowed annually until 1982.

Species Lists**TREES**

OTHERS: Bromus inermis, Arrhenatherum elatius, Dactylis glomerata, Poa compressa, Poa pratense, Potentilla recta, Solanum carolinense, Lotus corniculatus, Achillea millefolium, Dianthus armeria, Veronica officinalis, Chrysanthemum leucanthemum, Lepidium campestre, Fragaria virginiana, Stellaria graminea, Hieracium florentinum, Hieracium sp., Asclepias sp., Erigeron sp.

**FIELD #398**

Vegetation Structure

Red cedar and red maple are relatively abundant, some reaching 8 m in height, with other trees found along the edges. The ground cover is primarily mixed herbaceous and shrub species < 1 m high, with the shrubs dominant in the south end of the field.

### Environmental Parameters

The terrain is mostly flat, with no discernable slope or aspect. The soil is Hoosic gravelly loam; a deep, gravelly, well-drained soil formed on outwash.

### Historical Information

The field was pastured as part of the Pettit farm, which was abandoned late in 1939. The field has apparently not been managed since then, except in 1979, when it was mowed once.

## HERBACEOUS PLANTS

DOMINANTS: Andropogon scoparius, Solidago spp.

OTHERS: Asclepias tuberosa, Rumex acetosella, Oxalis stricta, Fragaria virginiana, Hieraracium florentinum, Achillea millefolium, Silene cucubalus, Chrysanthemum leucanthemum, Potentilla simplex, Solidago bicolor, Erigeron sp., Carex sp.

## FIELD #460

### Vegetation Structure

The field is dominated by a matrix of grasses and creeping plants, but shrub clumps and tree seedlings are common. Trees reaching 8 m in height are present, but are mostly confined to the edges and hedgerows. Tree seedlings are well-dispersed within the field.

### Environmental Parameters

The field mostly occupies a northeast-facing, nearly level, hilltop. A depression bisects this site along an east axis, with gentle slopes ranging up to 10°. The soil is primarily Hoosic gravelly loam, with no apparent bedrock exposed within the field.

### Historical Information

A stone wall runs along the east edge of the site, which is surrounded by woods. The field was part of the Pettit farm when purchased by the Carys in 1930. Abandonment from agriculture occurred in late 1939, and there has been no known management in the area since then.

DOMINANTS: Andropogon scoparius, Danthonia spicata, Lysimachia quadrifolia

OTHERS: Rumex acetosella, Hieracium florentinum, Fragaria virginiana, lichens (including some Cladonia), Potentilla simplex

**FIELD #510**Vegetation Structure

A mixed herbaceous cover is dominant and nearly complete, with only a single individual tree and sparsely distributed low shrubs (< 1 m high) growing at the south end of the field. Overall herbaceous cover is heterogeneous and patchy due to the nature of the management history of the site.

Environmental Parameters

The terrain is artificially flat, located on a hilltop with no exposed bedrock. Hoosic gravelly loam is the major soil type.

Historical Information

This field was part of the Pettit property until it was sold in 1930. The recent management history of this site eclipses any of its previous uses. The Arboretum has been using the area as a dumping site and tire field, and brush-burning is usually carried out during the winter. Gravel for the

Arboretum internal road system was stripped off this site, resulting in an approximately 2 m drop in relief, as well as levelling the terrain. A gravel pit was established in 1981 near the southwest corner. Mowing was done 2 to 3 times a year prior to 1982, and more recently only once a year.

### **FIELD #644**

### Vegetation Structure

Trees and shrubs are dominant, but distributed in patches. Trees are mostly assembled in copses toward the periphery, with two major rows crossing the field, up to 10m in height. Shrub thickets reaching 2 m high are common, with open spaces of exclusively herbaceous cover also present.

Environmental Parameters

The topography is mostly flat with gentle sloping areas not exceeding 5°. A pond occurs toward the northeast corner of the field. The soil is a Hoosic gravelly loam, on a deep, gravelly, well-drained outwash. No exposed rock was observed.

Historical Information

Abandonment of this land, which had been part of the Chase farm, occurred in 1932, followed by an approximately 25-year fallow period. Mrs. Cary had all dead elm trees cleared from the area around the pond at the northeast edge, as well as some selective cutting of woody vegetation. Horticulture crews have used the field to clip white pine branches for vegetation cover. This field may have been brushhogged after 1973, but was mowed from 1978 to 1982/83 and used as a site to study winter deer browse and deer repellants.

## FIELD #710

### Vegetation Structure

Trees dominate the site, reaching 10 m in height (predominately red cedars in a relatively dense array forming an open canopy). The shrub cover is sparse, rare in places and mostly composed of solitary individuals or clumps < 1 m high, with tall shrubs exceeding 2 m in more open, low areas. Herbaceous cover is mostly composed of grasses and mosses which are abundant throughout the understory.

### Environmental Parameters

The site topography is heterogeneous, with a hilltop on the southeastern edge sloping steeply (up to 30°) down to flat low areas adjacent to a small stream along the northwestern edge of the field. The hillside is northwest- to west-facing, with patches of exposed bedrock common on the upper slopes, sometimes projecting vertically out of the hill. The shallow, well-drained soil is a Nassau slaty silt loam, underlain by shale at depths of < 50 cm.

### Historical Information

This land was used as pasture when it was part of the Chase farm, until 1932. There has been little subsequent management beyond the possible removal of some dead elm trees in the 1960's.

## FIELD #714

Vegetation Structure

Large clonal populations of black locust and smooth sumac dominate this field. Most of the canopy consists of patches of trees up to 10 m in height with a shrub undercanopy reaching 2 m high. Herbaceous cover is composed primarily of grasses.

Environmental Parameters

The site is almost entirely flat, gently sloping from the road with slopes < 5°. The soil is a Dutchess gravelly silt loam.

Historical Information

This field was pastured during its ownership by the Chases, and possibly also used as an orchard. It was abandoned with their departure in 1932. Stone walls separate it from adjacent fields to the N, E, and S. A road for access ~~to the field~~ goes through the land, and it has been recently used as a small

## FIELD #715

Vegetation Structure

Trees are common near the west edge of the field, with black locusts along the roadside. Shrub thickets are abundant and dominant in a large fraction of the area.

Environmental Parameters

The site is mostly flat, with a southeast-facing slope reaching  $10^0$ . The soil is a Dutchess gravelly silt loam.

Historical Information

Stone walls form boundaries from adjacent fields to the north, east, and south. The field is a former orchard and pasture on the Chase farm. There has been no known management of this site since its abandonment in 1932.

## FIELD #719

Vegetation Structure

Trees up to 10 m in height are sparse but widely distributed along with seedlings throughout the field, particularly toward the west edge along the road. Shrub cover is patchy and less common than seedling density overall. Herbaceous cover is incomplete, with bare spots becoming common in some areas. Grasses and creeping shrubs dominate the herbaceous layer.

Environmental Parameters

The terrain is rolling, with gentle slopes up to 10° that are primarily west- to northwest-facing. Nassau slaty silt loam comprises the well-drained soils, typically underlain by shale < 50 cm. Small exposed bedrock outcrops are widespread but very sparsely distributed.

Historical Information

The field was once part of an orchard and was abandoned along with other areas of the old Chase farm in 1932, with no known management history since that time. The south edge is separated from former pastureland by a hedgerow and stone wall which extends along part of the east side, with woods present to the northeast.

Trees up to 10 m in height are present at the edges of the field, except for red cedar, which is well-distributed throughout the field. The plant canopy is mostly an herbaceous layer dominated by grasses and creeping plants in which low, solitary shrubs and seedlings are common.

Environmental Parameters

A northeast to southwest-running ridge is prominent in the western half of the field, forming a gentle south-facing slope reaching 10°. The soil is a Nassau slaty silt loam underlain by shale < 50 cm, with small areas of exposed rock on the ridgetop.

Historical Information

Bounded on all 4 sides by stone walls and adjacent fields, this land was used for pasturing up until 1932, when the Chase farm was abandoned. There has

been no known use of the land since that time.

FIELD # 788Vegetation Structure

An herbaceous matrix surrounds large clumps and thickets of shrubs on two ridges, separated by an open canopy of trees between the ridges.

Environmental Parameters

The terrain is dominated by a set of ridges running northeast to southwest. Open bedrock outcrops are common in patches on these ridges. The hillside is primarily southwest-facing, with slopes ranging up to 15°.

Historical Information

Stone walls are present to the south and west. This land was abandoned as part of the old Chase farm in 1932. No known management has occurred on the land since that time.

Herbaceous plants form a continuous matrix in which tall shrubs are common in thickets and dominant in much of the field. Trees up to 8 m in height are sparse and widespread throughout, but are most common at the periphery with abundant black locust trees toward the northwest corner.

Environmental Parameters

The field is on a south-facing hillside sloping moderately to 10°, with flat level areas both at the north edge and at the south edge by Wappinger's Creek. Pawlet silt loam forms the alluvial soil on the floodplain adjacent to the stream, with shallow Nassau slaty silt loam on till and deep Hoosic gravelly loam on glacial outwash. There is little visible exposed bedrock.

Historical Information

A stone wall is present in the thick hedgerow to the north, and the field is bounded by woods in the other directions. The field is adjacent to the old Henry farmhouse, and was planted until abandonment around the mid-1930's. Subsequently, the land has been unmanaged except for some recent cutting of black locust trees to provide posts for the Arboretum.

## FIELD #924

Vegetation Structure

This site is very heterogeneous, consisting of a mosaic of open woods and meadows with amorphous boundaries. Trees are abundant, up to 10 m high in a network separating meadow areas, but do not form a closed canopy except around the pond and stream. The overall shrub cover is low, forming sparse but widely distributed individual clumps. Little bluestem dominates the herbaceous layer in open areas.

Environmental Parameters

The terrain is hilly, with small hilltop areas separated by a permanent pond near the north edge, and a south-flowing outlet that becomes a temporary pond or marshy area in the center of this site. The hillside is south-facing, with slopes  $< 18^{\circ}$  and widespread but small patches of exposed bedrock. The soil is primarily a shallow Nassau slaty silt loam.

Historical Information

The land was part of the old Henry farm, and was used as pasture until it was abandoned in the early 1930's. Stone walls are present in hedgerow to the east and south, and to the north in the woods. The field has remained untouched since then, except possibly for some cutting to create a vista in the 1960's.

**OTHERS:** Lysimachia quadrifolia, Veronica officinalis, Achillea millefolium,  
Rudbeckia hirta, Hieracium florentinum, mosses, lichens (Cladonia cristatella  
 and other Cladonia)

**FIELD #935**Vegetation Structure

The vegetation is heterogeneous, composed of dominant trees reaching 6m in height in a herbaceous matrix, composed primarily of graminoids. An open hedgerow of hardwood trees occurs along a north to south axis toward the south-facing hillside. red cedar trees and saplings are common on the south and east exposures of the hill. Shrub cover is patchily distributed within the herbaceous layer as a relatively minor component of total cover.

Environmental Parameters

The terrain is mostly flat hilltop with steep slopes up to 30° at the south end and moderately sloping to woods to the W. Sparse exposed bedrock is located on the north (s) ridge and hill. Dutchess gravelly silt loam is the soil type of the till.

Historical Information

Stone walls are present to the S, W, and east in hedgerows, as well as to the north in the woods. At the N-most boundary of the old Henry farm, this land probably served as orchard and pastureland prior to abandonment around 1932. Management did not occur again until the 1960's when a vista was probably cut through at least part of this area, as there are some cedar stumps present. Infrequent brush-hogging was carried out between 1974 and 1980, with no subsequent management.

## FIELD #937

Vegetation Structure

Trees reaching 10 m in height are common throughout the field, with abundant tall shrubs solitary or in thickets up to 3 m high. Mixed sugar maple and american ash trees are prominent in a hedgerow along the ridge on the east side of the field. Grasses and dicots form a dense herbaceous layer.

Environmental Parameters

This is a large field, covering over 6 ha. Topography ranges from a low, wet area on the west side of the field (along Canoe Hill Road) to a ridgetop at the north corner of the field. Most of the field occurs along the hillside between between these two extremes. The deep, gravelly, well-drained soil is a Dutchess gravelly silt loam, along with some Pittstown gravelly silt loam, forming a more shallow acid soil with a clay fragipan. The slope is moderate, approaching 25° in the northwest corner of the field. Exposed bedrock is sparse but present in patches, especially in the northwest and southwest corners of the field.

Historical Information

Stone walls and hedgerows form boundaries on all sides of the field, which was tilled as cropland of the Henry farm. Abandonment occurred around 1932 (an old rusted car is still present in the southeast corner of the field). Management by the Arboretum to control woody plants (through brush-hogging) occurred between 1973 and 1982 in coordination with use of the site for deer repellent testing since 1978.

## FIELD #955

Vegetation structure

Woody plants dominate the structure of this field. Trees are mostly confined to the edges and central depression of this field, increasing in density toward the eastern edge. Clonal smooth sumac and black locust populations have proliferated in the northeast corner of the field. Shrubs are well-dispersed among the herbaceous cover, forming a loose matrix within the herbaceous plants. Seedlings are present in very low density. Little bluestem is the dominant herbaceous species.

Environmental Parameters

The field is located on a hilltop, and slopes of  $< 17^{\circ}$  lead to streams to the east and south. A distinct depression bisects the field along a north-south axis. The soil of the upper slopes is a well-drained Dutchess gravelly

silt loam, with deep, acid Pawlet silt loam in the alluvial soil adjacent to Wappinger Creek. Exposed bedrock is present on the east-facing steep slope and the extreme northeast corner of the field.

### Historical Information

This field was used principally as cropland prior to abandonment, which occurred after the Henry farm was leased to other renters in the mid- 1930's. A rock wall with barbed wire forms the north boundary, suggesting pasturing in the adjacent field. Active management was resumed when the Arboretum began brush-hogging once a year in 1973. This practice occurred sporadically between 1978 and 1982/83 while deer repellent testing was carried out on this land.

Achillea millefolium, Poa sp.

## FIELD #957

### Vegetation Structure

Shrub thickets reaching 3 m in height dominate parts of this field, with dense populations of Lonicera morrowii in the west end. Trees are mostly sparse, but become abundant in the east end where a tall clonal population of black locust trees (< 10 m in height) forms a canopy over extensive smooth sumac thickets. The herbaceous layer occurs throughout most of the field, but the grass composition is relatively low overall.

### Environmental Parameters

Flat, hilltop terrain characterizes the topography, with a gentle  $10^0$  slope to the west. A small, wet field lies adjacent at this end. The characteristic soil is Dutchess gravelly silt loam. Two small, minor patches of exposed rock are found at the east and west ends of the field.

### Historical Information

A barn area lies at the end of the field, separated by a barbed wire fence from the rest of the field. Remains of old farm equipment from this barn, which burned down during the 1940's, include buckets and an engine. Stone walls are in hedgerows to the north and south, and to the east in the woods. This field was most recently an orchard area and pastured by the Henrys and Wm. Braddock, who leased this area from the Carys until about 1937. There was little or no management by the subsequent tenant, and the field remained relatively untouched to the present, except for some cutting of black locust trees to provide posts for the Arboretum.

Andropogon scoparius

OTHERS: Stellaria graminea, Rumex acetosella, Hieracium florentinum, Carex  
sp., Saponaria officinalis, Cynanchum nigrum, Lotus corniculatus, Alliaria  
officinalis, Phleum pratense, Agropyron repense, Poa sp.

## FIELD #960

Vegetation Structure

A hedgerow to the south separates this field from field #972. The vegetation cover is largely composed of shrubs and herbaceous plants. Widely scattered individual trees up to about 8 m in height are present in a mixed array of species, reaching the highest density in the northeast corner of the field. Overall, shrubs occur in a patchy matrix of low thickets or isolated clumps of single species, surrounded by a mixed association of herbaceous plants. Tree seedlings are rare.

Environmental Parameters

The topography is characterized by flat hilltop areas with east- and west-facing slopes, reaching 12-15°. Dutchess gravelly silt loam is the major soil type, on deep, gravelly, well-drained till. Some exposed bedrock is present on the eastern edge of the field and north of the center in small patches.

Historical Information

This field was tilled as part of the Henry farm, and was purchased by the Carys in 1930. Stone walls are present both to the north and west in hedgerows. Abandonment from active agriculture probably occurred in the early 1930's, followed by an absence of management until the early 1970's. Brush-hogging to control or remove woody vegetation was carried out between 1973 and 1978 at least once a year, and sporadically continued through the winter of 1982-83 as part of a deer repellent testing program at the Arboretum.

## FIELD #969

Vegetation Structure

The field is dominated by herbaceous species and creeping woody plants, with shrubs present in localized thickets. Trees are primarily located toward the periphery of the field, except red cedar, which is sparsely present in more open spaces. Vegetation cover is absent in a few, sparsely distributed spots.

Environmental Parameters

The terrain is mostly flat to slightly rolling, with a gentle slope of  $< 10^0$  toward a low area at the southwest corner of the field. The characteristic soil is a Dutchess gravelly silt loam with some Nassau silty loam also present. Exposed bedrock is found primarily at the northeast end and southeast corner of the field.

Historical Information

Evidence of an old stone foundation and orchard is present, but the field was planted and pastured until the early 1930's as part of the Henry farm. This area was brush-hogged from 1973/74 to 1980. Logging undertaken as part of the CETA program occurred to the north in 1981, but there is no evidence of any use of the field in this operation.

## FIELD #972

### Vegetation Structure

Trees up to 5-8 m in height are scattered throughout the field in low density, but forming a patchy, open canopy in the east and southwest corners of the field. The shrub layer is patchy and relatively sparse overall, composed of only a few thickets and scattered individuals. The herbaceous cover is complete outside of these thickets, consisting mostly of grasses, particularly beneath the tree canopy.

### Environmental Parameters

The field is located on a hilltop and slopes facing south and east. A large bedrock outcrop faces due west with a steep slope reaching 35°. Small, sparse areas of exposed bedrock are found throughout the field. The soil is almost exclusively Dutchess gravelly silt loam.

### Historical Information

This field was probably planted as part of the old Henry farm, and abandoned around 1932. It is bounded on all four sides by stone walls. Brush-hogging occurred annually beginning in 1973, and was carried out in coordination with deer repellent testing from 1978 until 1982/83. Currently, small mammal traps are set up in part of the field. (1985)

### ACKNOWLEDGEMENTS

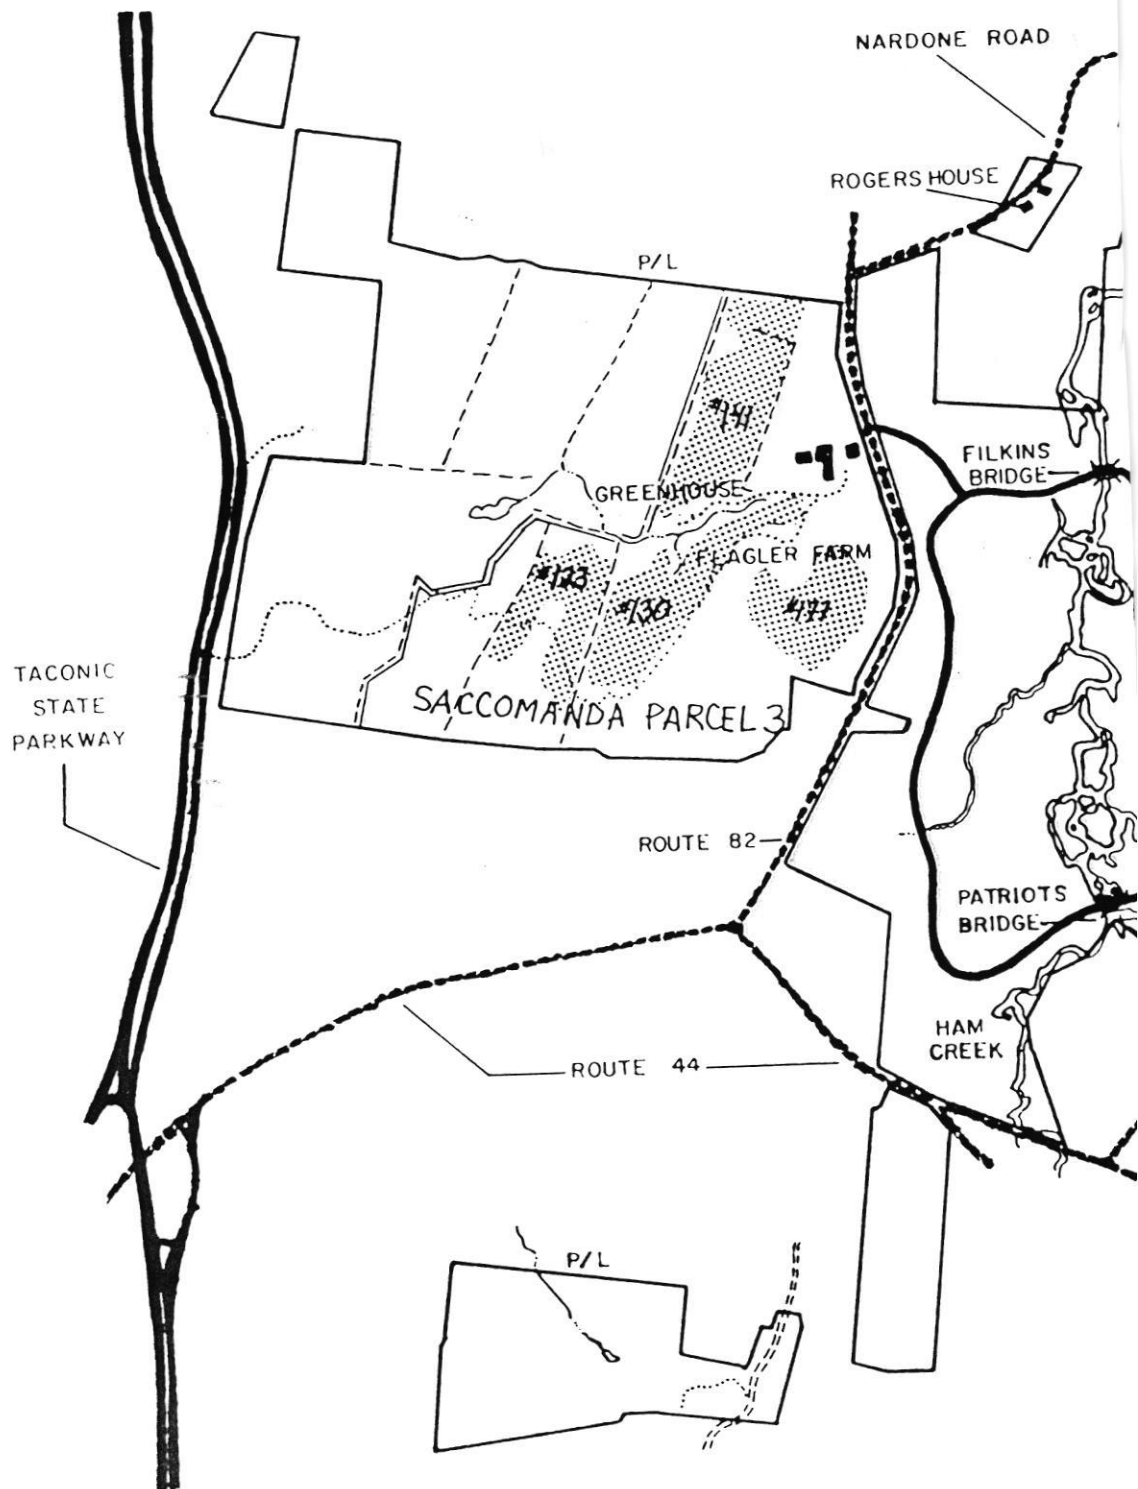

Many sources of information were used to compile histories of land-use for the fields covered in this study. We would particularly like to thank the members of the local community - Sally Gifford O'Brien, Wendell Fowler, Jim Henry, Katherine Lovelace and Harry Pettit - who agreed to be interviewed and provided us with essential information on former land-use patterns. Many members of the Arboretum staff, particularly Ray Winchcombe and Brad Roeller, provided information on management of the fields during the past 15 years. Financial support for this study was provided by the Mary Flagler Cary Charitable Trust. This study is a contribution to the program of the Institute of Ecosystem Studies, The New York Botanical Garden.

**TABLE 2.** Cover and percent frequency of woody and herbaceous species in 40 plots distributed among the major upland old fields of the Mary Flagler Cary Arboretum. Local cover is the mean cover of a species averaged over only those plots in which it occurred. Zero values indicate that the species was present in at least one plot, but was not encountered in the quadrats or along the transects used to measure actual cover.

**APPENDIX A: MAPS OF THE MAJOR UPLAND FIELDS**

SACCOMANDA FARM: FIELDS #123 - #177

Note: The grid square number for which the field was numbered is enclosed in a box.

PETTIT FARM: FIELDS #398 - #510

CHASE FARM: FIELDS #644 - #788

HENRY FARM: FIELDS #904 - #972

## APPENDIX B: LAND TRANSACTIONS INVOLVING THE UPLAND FIELDS

### Chase Parcels: Land Transactions

The Chases owned two farms surrounding Pettit Rd. and extending along Canoe Hill Rd.; the upper parcel (107 acres) included the fields used in this study. The Chases left in 1932, after which the Henrys leased the lower parcel of 98 acres for a short period to use as pastureland.

#### UPPER PARCEL

<u>Year</u>	<u>By</u>	<u>From</u>	<u>Document</u>	<u>Acreage</u>
1930	M.B. Cary	Chas and Mary Chase	deed 504:433	
1927	Charles Chase	C. VanBenshoten	475:321	107
1925	C. VanBenshoten T. Purcell, ref.	Pettit family members (mortgage dispute)	475:320	107

1896	Jane Hallock	heirs of Jas H. Hallock	287:203	
1856	Jas H. Hallock	Lewis E. & Jane Hallock	106:519	

### Henry Parcel: Land Transactions

The Henry farm covered about 187 acres and surrounded the lower part of Canoe Hill Road, north of Wappinger Creek, adjacent to the Chase farm to the north. They also owned a small parcel, either 31 or 41 acres, which was adjacent to the Gifford property, the west-most part of which was a woodlot. Another woodlot was located at the N corner of their property. The Henrys left in the early 1930's soon after the Chases. Their land was then leased to Wm. Braddock for 4-5 years, who did no planting and only used some of the land for pasture. The subsequent renters left the land abandoned, and did not use or otherwise manage it for any purpose.

#### Land acquisition record

<u>Year</u>	<u>By</u>	<u>From</u>	<u>Document</u>	<u>Acreage</u>
1930	M.B. Cary	James Henry	deed 504:452

1833	Wm. E. Newcomb	heirs of Wm. Tripp	51:75	167

### Pettit Parcel: Land Transactions

The ca. 177 acre Pettit farm was located on both sides of the north part of Canoe Hill Rd., near the intersection with Fowler Rd. The Pettits owned a tractor in the late 1930's, but it was not used much, if even at all, for tilling. There were two orchards, one south of Canoe Hill Rd., and two woodlots which totalled 40 acres, one in the northwest corner of their property and the other at the spur of their property extending south toward Tea House Hill. The whole property was originally divided into a major parcel and a small 5 acre parcel.

#### Land acquisition record

1802	John Sharpstone	Jacob Sharpstone	will B 345	166

### Saccomanda Parcels: Land Transactions

The Saccomandas sold their dairy farm, located at the present site of the greenhouse, to the Cary's in 1937. The property had originally been four separate parcels; all of the fields in this study were located in the 184 acre eastern parcel.

<u>Year</u>	<u>By</u>	<u>From</u>	<u>Document</u>	<u>Acreage</u>
